

SSO Access Guide - First-line checks

Owner: Identity Support | **Audience:** First-line support and workspace administrators | **Version:** 1.2

Scope. Use this guide when one or more users cannot sign in after single sign-on is enabled, changed, or migrated. It covers initial diagnosis only; it does not authorize support to modify the customer's identity-provider configuration.

First check. Confirm that the identity-provider email matches the user's workspace email address. Ask the workspace administrator to verify the SAML NameID mapping and confirm that the affected user belongs to the group assigned to the application. A mismatch in either field is a common cause of access failures after an SSO rollout.

Information to capture. Record the affected user's email domain, the time the failure began, whether the user previously signed in successfully, the customer-visible error message, and whether other users are affected. Do not request passwords, private keys, raw SAML assertions, access tokens, or identity-provider secrets.

Safe first-line response. Explain that the administrator should compare the identity-provider email, NameID mapping, and assigned group with the workspace configuration. Do not state that the platform caused the issue until Identity Support has reviewed the evidence.

SSO Access Guide - Escalation boundary

Actions support must not take. Do not disable SSO, reset identity-provider settings, change SAML mappings, alter group assignments, or bypass access controls. Those actions remain with the customer's workspace administrator or Identity Support under the approved process.

Escalate to Identity Support. Escalate when the whole workspace is blocked, multiple users report the same failure, the customer reports a production outage, the administrator confirms all expected settings, or the ticket indicates possible unauthorized access. Tag a widespread access issue as urgent.

Internal note checklist. Include the number of affected users, start time, error wording, verified email/NameID/group checks, customer time zone, and whether a workaround exists. State clearly what has been confirmed versus what is only suspected.

Resolution recording. If the administrator resolves the issue by correcting the email, NameID mapping, or assigned group, record the customer-confirmed change and outcome. Never store secrets or full identity-provider configuration in the ticket.

FAQ. A password reset is not a remedy for an SSO mapping failure. If a customer asks support to turn off SSO, route the request to the authorized workspace administrator instead of taking the action.
